Limited Use Label License for SUMOpro and SUMOstar fusion tag systems

The product and/or its derivatives are being furnished to the purchaser under the following conditions: by purchasing the product, the purchaser agrees to comply with the terms of this Limited Use Label License. The product is provided to purchaser for research use only. The purchaser of this product may not transfer or otherwise sell this product or its derivatives to a third party without the express written permission of LifeSensors, Inc., and no rights are given to the purchaser to use the product or its derivatives for commercial purposes as defined below.

Commercial purposes means any activity for which a party receives consideration and may include, but is not limited to, 1) use of the product or its derivatives in manufacturing, 2) use of the product or its derivatives to provide a service, information, or data, 3) use of the product or its derivatives for diagnostic purposes, 4) transfer or sale of vectors, clones, or libraries made with the product or derivatives of the product, 5) resale of the product or its derivatives, whether or not such product or its derivatives are resold for use in research.

Product use must follow compliance with all laws and regulations, including but not limited to current EPA, FDA, USDA, and NIH guidelines. THE MATERIALS WILL NOT BE USED IN HUMANS. Purchaser acknowledges that the product is experimental in nature and provided WITHOUT WARRANTY OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE OR ANY OTHER WARRANTY, EXPRESS OR IMPLIED. LIFESENSORS, INC. MAKES NO REPRESENTATION OR WARRANTY THAT THE USE OF THE PRODUCT WILL NOT INFRINGE ANY PATENT OR OTHER PROPRIETARY RIGHTS.

In no event shall LifeSensors, Inc. be liable for any use of the product by purchaser. Purchaser agrees to defend, indemnify, and hold harmless LifeSensors, Inc. its officers, employees, and agents from any loss, claim, injury, damage, expense, or liability (including attorney's fees), of whatsoever kind or nature, which may arise from or in connection with this Agreement, including but not limited to purchases, use, handling or storage of the product.

Background Ubiquitin and SUMO

In cells, proteins are tagged for degradation by ubiquitin and targeted to the 26S proteasome. In contrast, covalent modification of cellular proteins by the ubiquitin-like modifier SUMO (small ubiquitin-like modifier) regulates various cellular processes, such as nuclear transport, signal transduction, and protein stabilization. Ubiquitin-like proteins fall into two classes: the first class, ubiquitin-like modifiers (UBLs) function as modifiers in a manner analogous to that of ubiquitin. Examples of UBLs are SUMO, Rub1 (also called Nedd8), Apg8, and Apg12. The second class of proteins includes parkin, RAD23. and DSK2 and are designated ubiquitin-domain proteins (UDPs). These proteins contain domains that are related to ubiquitin but are otherwise unrelated to each other. In contrast to UBLs, UDPs are not conjugated to other proteins. Once covalently attached to cellular targets, SUMO regulates protein-protein and protein-DNA interactions, as well as localization and stability of the target protein. Sumoylation occurs in most eukaryotic systems, and SUMO is conserved from yeast to humans. SUMO and ubiquitin only show about 18% homology, but both possess a common three-dimensional structure characterized by a tightly packed globular fold with β -sheets wrapped around an α -helix.

SUMOstar Fusion Technology

Yeast SUMO (Smt3) fused with a protein of interest can dramatically enhance expression and promote solubility and correct folding of the protein. SUMOstar, a version of SUMO that is not recognized nor cleaved by natural desumoylases, has been developed primarily for eukaryotic systems. It has been known for a long time that ubiquitin exerts chaperoning effects on fused proteins in *E. coli* and yeast, increasing both yield and solubility. Attachment of a highly stable protein (ubiquitin or SUMO) at the N-terminus of a partner protein confers stability to the recombinant fusion protein, subsequently increasing its yield. The enhanced solubility demonstrated by fusing Ub/Ubls to the N-terminus of the protein-of-interest may be explained by improved/more rapid folding of the POI resulting from nucleation by the Ubl.

Recombinant Protein Purification and SUMOstar Protease

While ubiquitin fusion has been known for many years to enhance protein expression, its utility as a protein purification modality is compromised by the inefficient nature of ubiquitin hydrolase, or protease – the enzyme that releases the partner protein from ubiquitin by hydrolyzing the peptide bond. In addition, ubiquitin is not a convenient tag in eukaryotic cells since ubiquitinated proteins are targeted for degradation by the proteasome. Other commonly used proteases such as thrombin, enterokinase, rhinovirus proteases, and TEV, do not cleave all fusions efficiently and, moreover, can generate unnatural N-termini by leaving residual amino acids at the cleavage site.

The establishment of the SUMOpro system is largely due to the nature of the protease Ulp1, a SUMO protease equivalent of ubiquitin protease. Ulp1 is superior when compared with other proteases commonly used in recombinant protein production, as it recognizes the Smt3 structure at the N-terminus of the partner protein and cleaves the junction irrespective of the N-terminal sequence of the protein (except proline). Also, Ulp1 has not been observed to cleave indiscriminately within the protein-of-interest. Based on Ulp1, LifeSensors, Inc. has engineered a cognate protease for the cleavage of the otherwise resistant SUMOstar tag, SUMOstar Protease. SUMOstar protease retains all the advantages of Ulp1, and largely exhibits the same characteristics in terms of activity, robustness, and tolerance of wide ranging conditions.

About the pE-SUMOstar vector

This vector is fully compatible with the pET expression system, allowing for tightly regulated expression of heterologous proteins in BL21(DE3) or related *E. coli* strains. The plasmid contains a selective marker for either resistance to ampicillin (1011A) or kanamycin (1010K). The use of pE-SUMOstar facilitates later expression efforts in SUMOstar eukaryotic expression vectors, if required.

Advantages

- 1) Convenient, directional cloning of gene-of-interest (GOI) in frame with SUMOstar fusion tag.
- 2) SUMOstar fusion can dramatically enhance recombinant protein expression and solubility.
- No known case of SUMOstar Protease cleaving within the fused POI.
- SUMOstar Protease cleavage yields native protein with a desired N-terminus (except proline).

Components

The SUMOstar Expression System provides the reagents to express a protein of interest as a linear chimera with the SUMOstar protein tag. The SUMOstar Expression System contains the following four components.

pE-SUMOstar (T7; Amp or Kan)

Size: $20 \mu g (0.5 \mu g/\mu l)$ Buffer: 10mM Tris, pH 8.0

SUMOstar Protease 1 (Cat. No. 4110)

500 Units (10 units/µl) Size: Buffer: 25 mM Tris, pH 7.5 150 mM NaCl 2mM DTT 10% glycerol

SUMOstar Protease Control Protein (Cat. No. 5010)

100μg (5.0μg/μl) Size: Buffer: PBS, pH 7.2

Affinity purified AntiSUMO/SUMOstar Antibody (Chicken IgY, Cat. No. AB7002)

50 µg,(1.0 mg/ml) Buffer: PBS, pH 7.2

Storage

pE-SUMOstar Vector (T7; Amp or Kan)

Store vial at -20° C or below.

SUMOstar Protease

Store -80° C. Avoid multiple freeze/thaw cycles.

SUMOstar Control Protein

Store vial at -80° C. Avoid cycles of freezing and thawing.

AntiSUMO/SUMOstar Antibody

For short-term use (several weeks), store at 4°C. Long-term storage should be at -80°C.

Cloning

Background

The pE-SUMOstar vector is provided as a circular plasmid. For cloning, the vector must be digested with Bsal (a.k.a.Eco31l) restriction endonuclease. This Class IIS restriction enzyme recognizes non-palindromic sequences and cleaves at sites that are removed from their DNA recognition sequences. The latter trait gives Class IIS enzymes two useful properties. First, when a Class IIS enzyme recognition site is engineered at the end of a PCR primer, the site is removed from the PCR product when digested, meaning that there will be no additional nucleotides between SUMOstar and your gene-of-interest (GOI). Second, overhangs created by Class IIS enzymes are template-derived and thus unique. In the case of pE-SUMOstar, digestion with Bsal generates ACCT (SUMO3 fusion juncture) at the 5' end and CTAG (Xbal) at the 3' overhang. Appropriate primer design then allows for convenient directional cloning.

Forward Primer Design (Cloning)

To clone your gene of interest into the pE-SUMOstar vector, it must be amplified by PCR with primers designed to specifically work in the above cloning strategy.

Below is an example of forward primer design incorporating a Bsal Class IIS restriction site.

Bsal: 5' - NN GGTCTCNAGGT XXX NNN NNN NNN NNN NNN NNN-3'

In this primer, GGTCTC is the Bsal recognition sequence, N is any nucleotide, and AGGT will be the overhang generated upon Bsal digestion. This sequence ends with GGT (the last codon of the SUMOstar tag), followed by XXX, the first codon of your GOI. Additional nucleotides may be required for the primer to anneal specifically to your GOI during PCR amplification.

If your GOI already contains a Bsal site, then another Class IIS enzyme and site may be used instead. Below are examples of forward primers for some of these enzymes/sites:

Aarl 5' - NN CACCTGCNNNNAGGT XXX NNN NNN NNN NNN NNN NNN NNN 3'

BbsI: 5' - NN GAAGACNNAGGT XXX NNN NNN NNN NNN NNN NNN - 3'

Bbvl: 5' - NN GCAGCNNNNNNNNAGGT XXX NNN NNN NNN NNN NNN NNN 3'

BfuAI: 5' - NN ACCTGCNNNNAGGTXXX NNN NNN NNN NNN NNN NNN 3 BsmBI: 5' - NN CGTCTC NAGGT XXX NNN NNN NNN NNN NNN NNN-3

BsmAI: 5' - NN GTCTCNAGGT XXX NNN NNN NNN NNN NNN NNN 3 Bsal: 5' – NN **GGTCTC**N <u>AGGT</u> XXX NNN NNN NNN NNN NNN NNN 3

BsmFI: 5' - NN GGGACNNNNNNNNNNNAGGT XXX NNN NNN NNN NNN NNN NNN NNN 3 5' – NN GGATGNNNNNNNNAGGT XXX NNN NNN NNN NNN NNN NNN 3

SfaNI: 5' - NN GCATCNNNNNAGGT XXX NNN NNN NNN NNN NNN NNN-3

NOTE: As a general practice, we recommend that two or more bases (any sequence) be added to the 5' end of each primer to allow more efficient cleavage of the PCR product, since some restriction enzymes cleave poorly when its recognition sequence is at the extreme end of a DNA fragment.

Reverse Primer Design (Cloning Strategy 1)

The reverse primer should contain one of the restriction enzyme sites from the vector MCS, allowing directional cloning of your GOI. We recommend that Xbal be employed as the restriction site in the reverse primer of your PCR product. If your insert contains an Xbal site or if the digestion of the PCR insert with Bsal alone is preferred for any reason, please see Strategy 2 below. Upon digestion of this PCR product with Bsal (5') and Xbal (3'), a fragment will be generated having overhanging sequence complementary to the expression vector linearized with Bsal alone (recall that Bsal digestion yields an Xbal site at the 3' overhang).

An example of a reverse primer for this purpose is:

```
Xbal: 5' – NN TCTAGA TTA XXX NNN NNN NNN NNN NNN ... – 3'
```

where TCTAGA is the Xbal recognition sequence, TTA is the reverse complement of the stop codon TAA, XXX is the reverse complement of the final codon, followed by the remainder of your GOI. Again, it is recommended that extra bases be added to the 5' end, as noted above.

Reverse Primer Design (Cloning Strategy 2)

If for any reason Bsal/Xbal is not a viable option, some flexibility exists in reverse primer design. For example, an Xbal overhang can be generated in your PCR product without Xbal digestion, avoiding problems stemming from having an Xbal site within your GOI. Incorporation of a Bsa1 site (or any other Class II Restriction Enzyme listed above) in front of the Xbal sequence allows for digestion with Bsa1 enzyme yielding the same (5') CTAG overhang.

An example of a reverse primer for this purpose is:

```
Bsal/Xbal:
               5' - NN GGTCTC TCTAGA TTA XXX NNN NNN NNN NNN NNN... - 3'
```

where GGTCTC is the Bsal recognition site that directs cleavage and generation of the overhang CTAG. Again, TTA is the reverse complement of the stop codon TAA, XXX is the reverse complement of the final codon, followed by the remainder of your GOI.

A number of alternative restriction sites to Xbal (for either Strategy 1 or 2) are present in the MCS of the vector. Please refer to the polylinker map for more information.

Preparation of Insert

After determining the cloning strategy to be employed from those outlined above, generate your PCR product with a thermostable polymerase according to the manufacturer's instructions. For maximal sequence integrity during PCR, the use of thermostable polymerases capable of proof reading activity (e.g. Pfu, Stratagene; DeepVent, New England Biolabs; or Tag HIFi, Invitrogen) is recommended. After purification with standard techniques (Sambrook, et. al.), digest the PCR product with the desired restriction enzymes (according to the manufacturer's instructions). The PCR product is now ready for direct cloning into pE-SUMOpro. Alternatively, the PCR product can be ligated into a sub-cloning vector (e.g. pBluescript) and sequenced prior to this step.

Preparation of Vector

The pE-SUMOstar vector is provided as a 20µg aliquot. It can be digested directly with restriction enzymes according to the desired strategy outlined above. Using standard techniques, (Sambrook, et. al.) purify the digested plasmid for ligation.

DNA Ligation

For ligation of the prepared insert into the digested vector, T4 DNA ligase and standard ligation protocols should be employed (Sambrook et al). Because cloning is directional, alkaline phosphatase treatment of vector should be unnecessary, but may be beneficial in lowering background of (re-ligated) single digested plasmid. The T4 DNA Ligase should be used as described by the manufacturer (e.g. MBI Fermentas, New England Biolabs, Roche, Stratagene, Promega).

Transformation

Following the manufacturer's recommendations, the ligation mixture can be transformed into competent E. coli by either chemical transformation or electroporation. Standard bacterial strains (e.g. DH5α, TOP10, etc.) should be used as they show a high propensity for DNA uptake, and have abolished RecA and EndA activity. Selection of clones containing the desired product should be in the presence of ampicillin (50-100µg/ml). For construct integrity, propagation in E. coli should always be in the presence of the selective agent.

Identification of Positives Clones

With directional cloning, positive identification can easily be accomplished by PCR screening using external priming sites present in the vector:

> 5' TAATACGACTCACTATAGG 3' T7 forward T7 terminator 5' GCTAGTTATTGCTCAGCGG 3'

This can be done either on purified plasmid DNA or by so-called "colony PCR." Plasmid clones can also be checked by restriction endonuclease digestion. Prior to generation of baculovirus, the integrity of the PCR generated gene-of-interest should be verified by DNA sequencing.

Expression

Transformation

For expression of the SUMOstar fusion protein, it is necessary to transform the confirmed plasmid clone into an E. coli strain containing the DE3 lysogen. The BL21 derived strains are particularly useful for protein expression as they contain mutations in ompT and lon, which abolish protease activity that could degrade your expressed protein. It is also possible to transfect the bacteria with the helper phage, which can be useful for expressing toxic proteins. The transformation procedure into these cells should be based on your manufacturers' protocols. NOTE: the transformation efficiency of DE3 strains of E. coli is normally lower than the cloning strains.

Small scale expression studies and optimization

Prepare LB containing the appropriate antibiotic for your pE-SUMOstar vector, as well as any antibiotic that may be necessary to maintain helper plasmids. In addition, the inclusion of 0.2% dextrose or glucose will help suppress heterologous expression and maintain plasmid integrity. Inoculate 2-3ml of broth with an isolated clone containing your confirmed plasmid. Grow overnight at 37C to a saturated culture at >200 RPM.

Determine optical density (600nm) of overnight culture, and dilute cultures into 2-3ml of fresh LB/antibiotic/dextrose. Shake vigorously at >200RPM. Proper aeration is crucial for maximal protein expression and culture viability. Starting density should be 15 to 30-fold lower than desired induction OD (0.015 OD ml-1 for an induction OD ml-1 of 0.5) to ensure maintenance of plasmid integrity. Optimizing expression of SUMO3 fusion protein may require altering induction temperature (e.g. 37, 30, or 20C), time (4 hours to overnight), and/or cell density (0.4 to 0.8 OD ml-1). Titration of the IPTG (0.05 - 1mM) may also be required. It is always advantageous to screen multiple clones for protein production.

Large scale expression

Using an overnight seed culture (see above), inoculate 1L of antibiotic and dextrose containing media. Grow cells with vigorous shaking at 37°C. Induce under optimized parameters (see above) with IPTG when the culture is in mid-log phase (OD between 0.4-0.6 at 600nm). At the desired time, harvest the cells by centrifugation at 5000 rpm. The cell pellet can be resuspended in lysis buffer and immediately processed for protein purification (see below). Alternatively, the pellet can be stored at -80°C indefinitely.

Purification

Cells can be lysed by a number of ways such as freeze thaw, sonication, homogenization enzymatic lysis, or a combination of the aforementioned methods. Lysis should be performed at a pH optimal for the first step of purification. The pH should be maintained between pH 7.0 and 8.0. Protease inhibitors such as PMSF should be included if you fear your protein is susceptible to aberrant protease activity, Complete tablets without EDTA (Roche) offer inhibitors to a broad range of proteases.

7

The presence of a HIS₆ tag at the N-terminus of the SUMOstar protein sequence allows for initial purification of fusion proteins by IMAC. **All purification steps should be carried out at +4C**. Follow the resin/column manufacturer's instructions for specific details.

Cleavage

Background

SUMOstar Protease 1, a highly active and robust recombinant protease, cleaves SUMOstar from recombinant fusion proteins. Unlike thrombin, EK, or TEV proteases, whose recognition sites are short, linear sequences, SUMOstar Protease 1 recognizes the tertiary sequence of SUMOstar. As a result, SUMOstar Protease 1 does not cleave within the protein of interest. SUMOstar Protease 1 is consistently active over a broad range of temperatures (30°C is optimal), pH [5.5 – 9.5], and ionic strengths.

Unit Definition

One unit of SUMOstar Protease 1 cleaves 90-100 µg of SUMOstar Protease 1 Control Protein in 1 hour at 30°C.

Digestion of SUMOstar fusion tag

- Dialyze IMAC purified SUMOstar fusion proteins (4°C) against 20 mM HEPES, 150 mM NaCl, pH 7.5 (or PBS, 7.2). If the dialysis volume does not exceed >100-fold sample size, multiple buffer changes (each 4h or greater) should be employed to effectively remove salts or detergents.
- 2. Add SUMOstar Protease 1 (1U per 100 μg of substrate) and incubate at 30°C for 1 h in the presence of 1-5mM dithiothreitol (DTT).
- 3. In addition, the following guidelines may be helpful:
 - If your protein of interest is sensitive to reducing agents, a less aggressive agent (e.g. BME or TCEP) can be used. Longer incubation times may be required.
 - ii. If low cleavage efficiency is observed, consider increasing the time and/or amount of SUMOstar Protease. Overnight at 4°C, for example, may be convenient during the initial dialysis step.
 - iii. Consider adding SUMOstar Protease 1 incrementally throughout the time course of the reaction.
 - iv. If a fraction of the fusion protein is mis-folded or aggregated, it may be resistant to digestion.
 - v. Consider reaction conditions or buffer components (e.g. salt, pH) that are known to affect your POI.

Removal of SUMOstar fusion tag and SUMOstar Protease 1

SUMOstar and SUMOstar Protease 1 both contain HIS_6 tags at their N-termini; therefore, SUMOstar and SUMOstar Protease 1 can be easily removed from the cleavage reaction by IMAC. The recombinant protein-of-interest is recovered in the flow through from such an additional IMAC step. Assess the quality of protein product by SDS-PAGE. If the protein is in the appropriate buffer it can be directly used, or further purification steps can be employed.

Controls and Validations

SUMOstar Control Protein

SUMOstar Control Protein is a recombinant fusion protein that contains the SUMOstar tag fused to a polypeptide, and can be used to control for SUMOstar Protease 1 activity. Incubation of 1 Unit of SUMOstar protease 1 with 100µg of SUMOstar Control Protein should result in >90% cleavage after 1hour at 30°C. Please note that the SUMOstar tag migrates at ~15-20kDa by SDS-PAGE following cleavage, with uncleaved SUMOstar Control Protein 1 running at ~40-50 kDa, depending on acrylamide percentage and reference standards employed.

Digestion of Control Protein

- 1. Incubate SUMOstar Protease 1 and SUMOstar Control Protein (1U per 100µg) for 1h at 30°C.
- 2. Add 5X SDS-PAGE sample prep buffer to digestion reaction.
- 3. Heat sample at 95°C for 5 min This heating step is essential to insure complete denaturation of the control protein.
- 4. Analyze cleaved SUMOstar Control Protein (5-10μg) by SDS-PAGE and Coomassie staining.

Western Blots

Anti-SUMO/SUMOstar is an affinity purified hen polyclonal IgY antibody that reacts with SUMOstar in Western blot and ELISA applications. For immunoblotting, a 1:1,000 to 1: 5,000 dilution is recommended. At these dilutions, 10-50ng of SUMOstar Control Protein should be detectable as a control. For ELISA a 1:5,000 to 1:25,000 dilutions is recommended. Optimal dilutions for other applications should be determined empirically.
